

## Extending Relay Life by Switching at Zero Cross

*Author: Stephen Allen  
Microchip Technology Inc.*

### INTRODUCTION

This short technical brief describes how to implement a Zero-Cross Detect feature on the PIC16F1708 microcontroller. This will also be used to switch a 220V relay to a 220 volt AC motor. Switching the relay at the zero-crossing point reduces spark across the contacts, extending relay life, and also reduces EMI. Switching at the zero-crossing point reduces EMI in both relays and high-voltage solid-state switches.

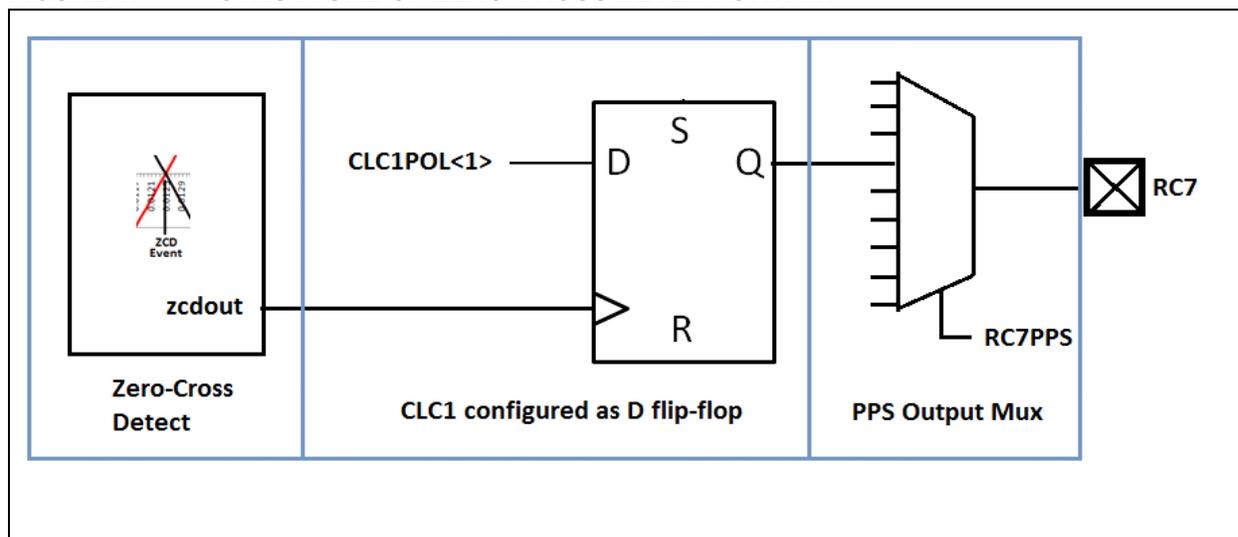

This application also demonstrates the “Core Independent Peripherals” concept, wherein interconnected peripherals are set up in advance of events, allowing fast switching with no processor interruption.

The zero-crossing detect event is routed through the CLC module to cause the switch to happen within microseconds of the zero-cross detect event occurring. Making use of the CLC for this function has numerous benefits:

- Fast response to the zero-crossing event:
  - No CPU intervention required
  - Switching speed is independent of processor speed
  - Switch occurs on microsecond scale
- It frees CPU to handle other processes while events occur.
- It can operate while device is in Sleep to lower current consumption.

The zero cross has been structured such that the main program requests the switch, and the switch will occur at the next zero-cross rising edge event. The flip-flop receives its clock from the zero-cross detect output signal. The data into the flip-flop is controlled through the CLC1POL<1> bit. The data is routed to the RC7 output pin through the RC7PPS MUX.

**FIGURE 1: STRUCTURE OF ZERO-CROSS DETECT SWITCH**

This technical brief will provide the implementation for a motor switch. The user can switch the motor off and on with a momentary button press. The relay will be opened and closed at the zero-crossing point in order to extend the life of the relay contacts and reduce EMI. Switching at zero cross also has applications in power-factor correction.

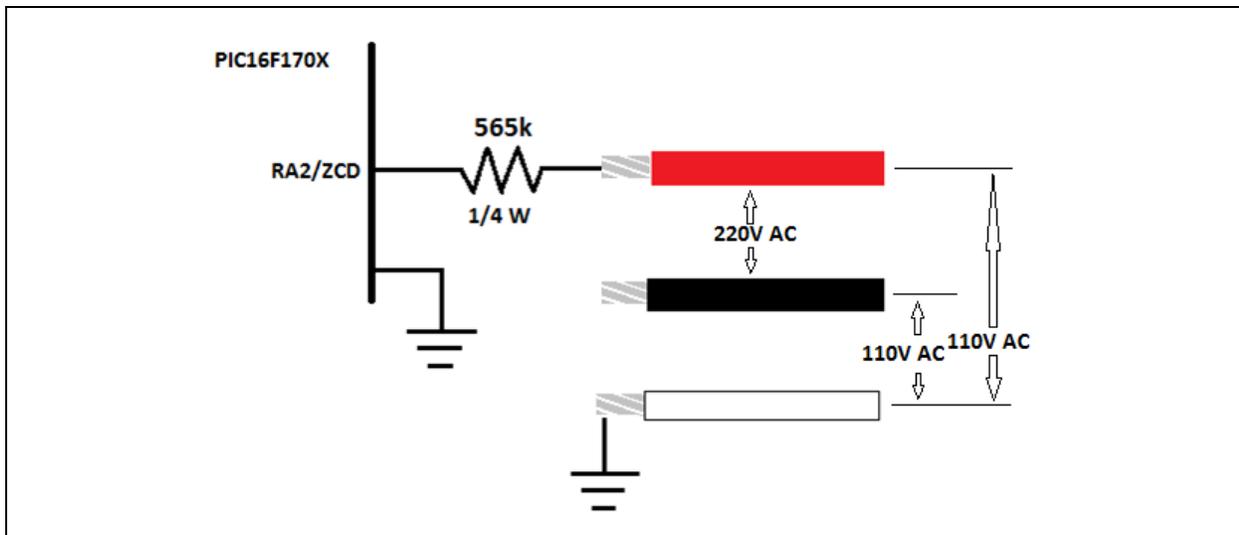

## RESOURCE REQUIREMENTS

**TABLE 1: RESOURCE REQUIREMENTS FOR ZERO-CROSS SWITCHING**

CLC modules	1
RAM	1 byte
Program memory	119 of 4096 locations

PIC16F170X products are equipped with a zero-cross detect circuit. The zero-cross detect feature requires the use of one high-value resistor. It is important to use a large resistor to prevent overcurrent/overvoltage from damaging the PIC® device. The circuit diagram for zero-cross detect is shown below (Figure 2):

**FIGURE 2: CONNECTION DIAGRAM FOR ZERO-CROSS PIN (RA2/ZCD) TO HIGH-VOLTAGE MAINS**

Note that the zero-cross detect pin has been hooked to the red (hot) wire through the 565 kΩ resistor. It could optionally be hooked to the black (hot) wire. It is necessary that the ground be hooked to the white (common) wire.

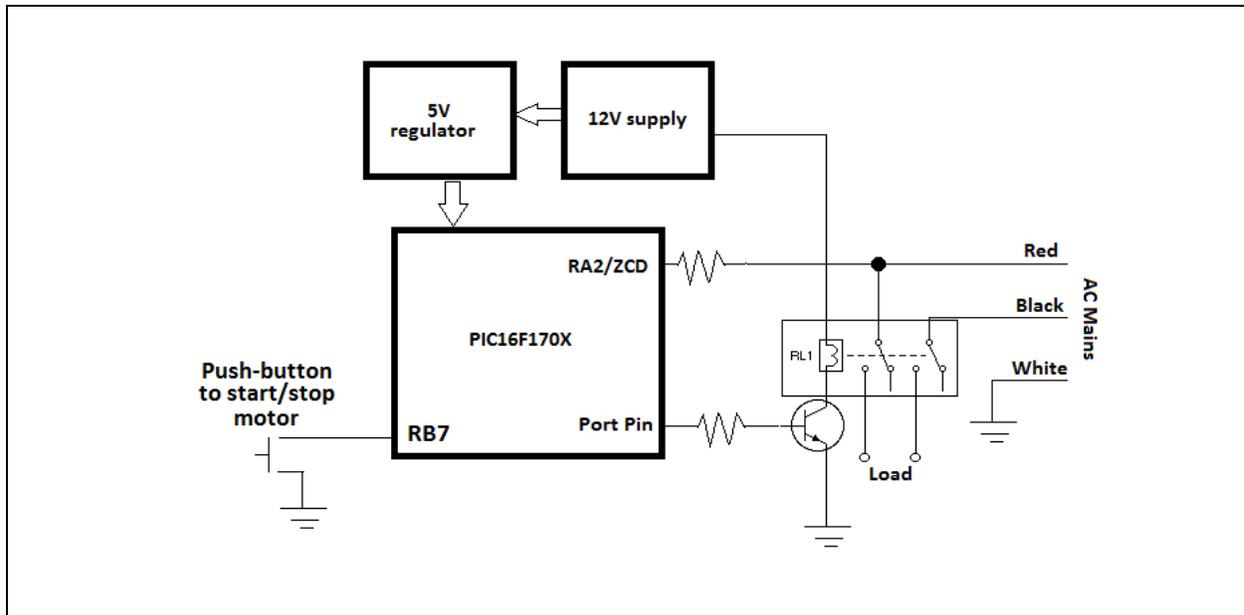

The RA2/ZCD pin should nominally sink/source 300 μA maximum. For a 120V (RMS) sine wave, it will have a peak of  $(120 * 2^{(1/2)}) = 169.7V$ , using Ohm's law:

$$V/I = R = 169.7/300 \mu A = 565 \text{ k}\Omega$$

The zero-cross detect peripheral has the option of generating interrupts on positive and negative-slope zero crossings. Two different power modes (High and Low) give flexibility in managing power consumption.

For this example, we are going to switch a 220V relay with a 12V DC coil. A push button switch (connected to pin RB7) is configured with an internal weak pull-up. The block diagram below (Figure 3) shows the primary connections:

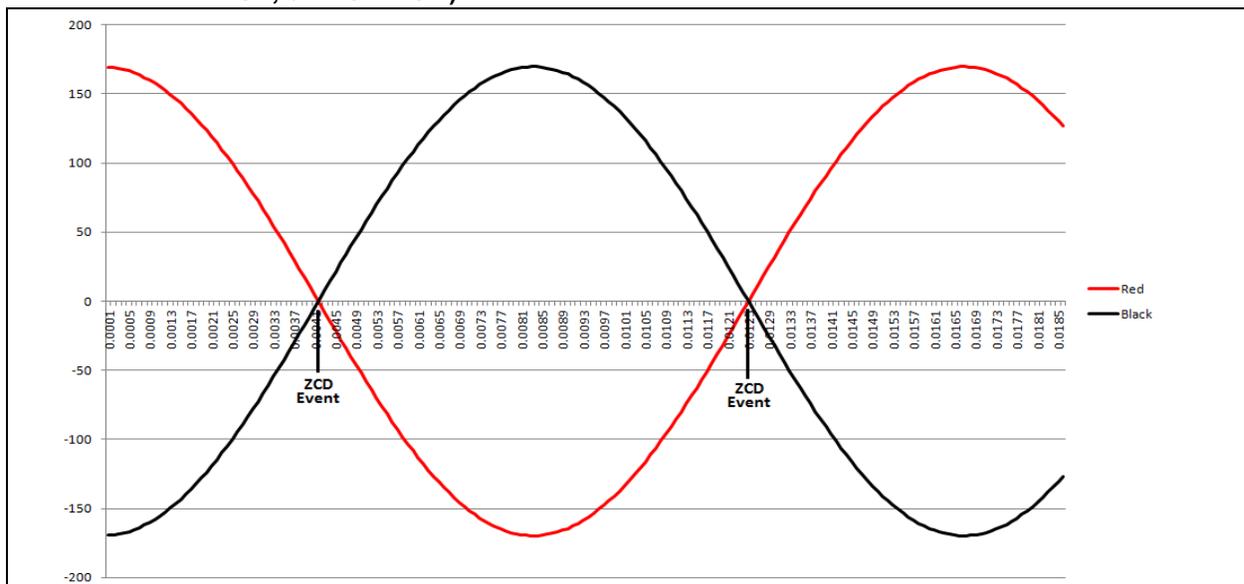

**FIGURE 3: SCHEMATIC DIAGRAM FOR ZERO-CROSS DETECT MOTOR SWITCHING**

## AC VOLTAGE WAVEFORMS (60 Hz)

The voltages on the red and black power connections are sine waves which are 180° out of phase with each other. The graph below (Figure 4) shows AC waveforms and the zero-crossing point. Note that if we switch at the zero-crossing point for one of the “hot” wires, it will be the same as the zero-crossing for the other “hot” wire. 110V (RMS) is the voltage of red or black with respect to the center line. It is easy to see that by taking the potential between both wires (red and black) you have doubled the amplitude of voltage difference (220V RMS).

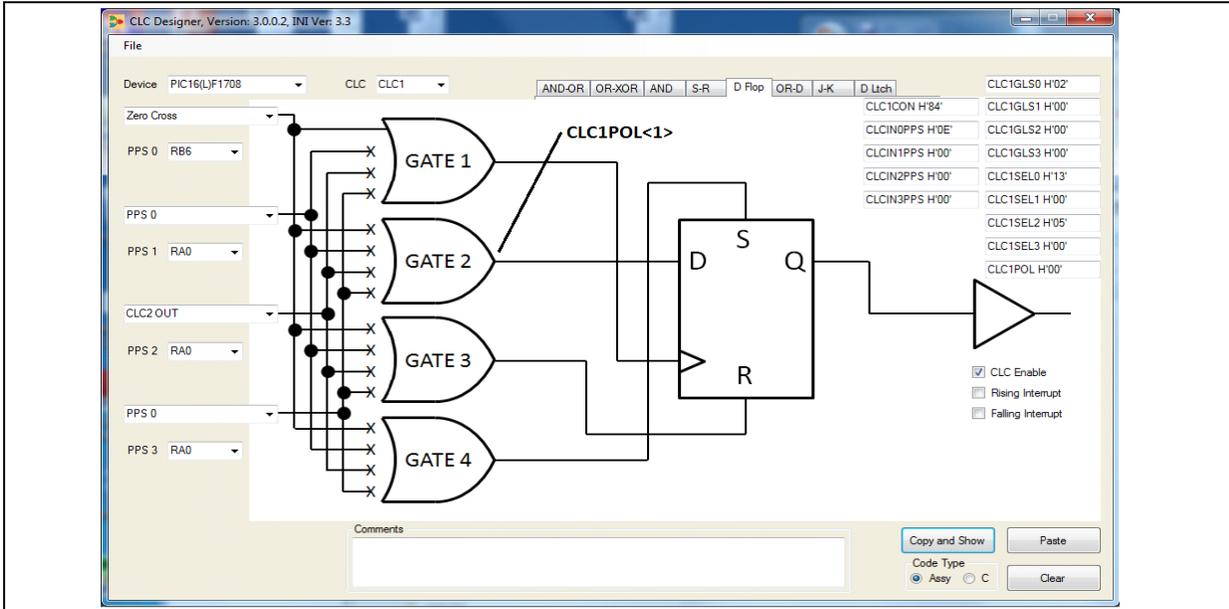

**FIGURE 4: 60 Hz AC MAIN WAVEFORMS AS A FUNCTION OF TIME (RED - HOT, BLACK - HOT, 0 - COMMON)**

## CLC CONFIGURATION

To switch near the zero-crossing point, we are feeding the clock of a D flip-flop with the zero-cross signal. The screen shot below (Figure 5) shows CLC1 configured as a D flip-flop with the clock fed from the zero-cross signal, and the data is provided via the CLC1POL<1> bit.

**FIGURE 5: CLC DESIGNER TOOL WITH CLC1 CONFIGURED AS D FLIP-FLOP**

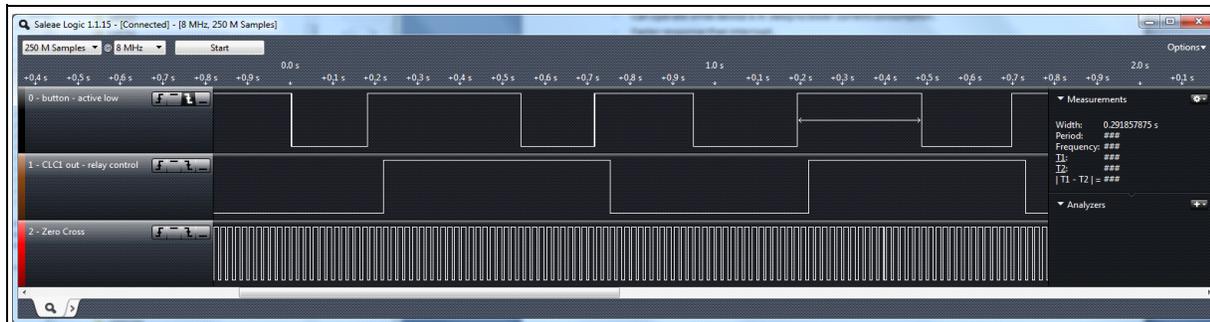

The logic waveform below (Figure 6) shows the following signals:

- Push button (active-low with internal pull-up from PIC device)
- Relay switching signal
- Zero-cross detect signal (brought out on port pin through the CLC module).

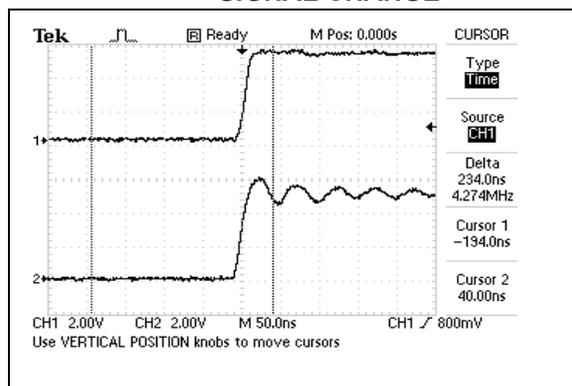

Notice that after each button press, there is a short delay to debounce the button, and then the state of the relay toggles. This allows a momentary push button to turn a motor on/off with successive presses. The change in CLC1OUT occurs on the rising edge of the zero-cross signal.

**FIGURE 6: WAVEFORM SHOWING MULTIPLE BUTTON PASSES AND RELAY OUTPUT TOGGING**

The next scope plot shows a zoomed-in view of the switch taking place at the zero-crossing point (Figure 7). The delay between the zero-cross signal and “CLC1OUT” is solely gate propagation delay and is independent of the processor clock. The signals are almost simultaneous because the zero-cross signal is internal to the PIC device. Propagation delay in the CLC is negligible, but each signal sees the same delay at the respective output pad.

**FIGURE 7: RELATIVE TIMINGS BETWEEN ZERO-CROSS RISING EDGE AND OUTPUT SIGNAL CHANGE**

## CONCLUSION

It is our hope that this technical brief provides a starting point for developing applications using the zero-cross detect peripheral. Switching at zero cross reduces EMI. This may provide cost reductions for some applications by reducing PCB noise and filtering components.

**Note the following details of the code protection feature on Microchip devices:**

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.
